SVM with Explicit Feature Map

- Let $\psi : \mathcal{X} \rightarrow \mathbb{R}^d$ be a feature map.
- The SVM objective (with explicit feature map):

$$\min_{w \in \mathbb{R}^d} \frac{1}{2} \|w\|^2 + \frac{c}{n} \sum_{i=1}^n \max(0, 1 - y_i w^T \psi(x_i)).$$

- Computation is costly if d is large (e.g. with high-degree monomials)
- Last time we mentioned an equivalent optimization problem from Lagrangian duality.

SVM Dual Problem

- By Lagrangian duality, it is equivalent to solve the following dual problem:

$$\begin{aligned} \text{maximize} \quad & \sum_{i=1}^n \alpha_i - \frac{1}{2} \sum_{i,j=1}^n \alpha_i \alpha_j y_i y_j \psi(x_j)^T \psi(x_i) \\ \text{s.t.} \quad & \sum_{i=1}^n \alpha_i y_i = 0 \quad \text{and} \quad \alpha_i \in \left[0, \frac{C}{n}\right] \quad \forall i. \end{aligned}$$

- If α^* is an optimal value, then

$$w^* = \sum_{i=1}^n \alpha_i^* y_i \psi(x_i) \quad \text{and} \quad \hat{f}(x) = \sum_{i=1}^n \alpha_i^* y_i \psi(x_i)^T \psi(x).$$

- Key observation:** $\psi(x)$ only shows up in **inner products** with another $\psi(x')$ *for both training and inference*.

Compute the Inner Products

Consider 2D data. Let's introduce **degree-2 monomials** using $\psi : \mathbb{R}^2 \rightarrow \mathbb{R}^3$.

$$(x_1, x_2) \mapsto (x_1^2, \sqrt{2}x_1x_2, x_2^2).$$

The inner product is

$$\begin{aligned}\psi(x)^T \psi(x') &= x_1^2 x_1'^2 + (\sqrt{2}x_1x_2)(\sqrt{2}x_1'x_2') + x_2^2 x_2'^2 \\ &= (x_1x_1')^2 + 2(x_1x_1')(x_2x_2') + (x_2x_2')^2 \\ &= (x_1x_1' + x_2x_2')^2 \\ &= (x^T x')^2\end{aligned}$$

We can calculate the inner product $\psi(x)^T \psi(x')$ without accessing the features $\psi(x)$!

Compute the Inner Products

Now, consider **monomials up to degree-2**:

$$(x_1, x_2) \mapsto (1, \sqrt{2}x_1, \sqrt{2}x_2, x_1^2, \sqrt{2}x_1x_2, x_2^2).$$

The inner product can be computed by

$$\psi(x)^T \psi(x') = (1 + x^T x')^2 \quad (\text{check}).$$

More generally, for features maps producing monomials up to degree- p , we have

$$\psi(x)^T \psi(x') = (1 + x^T x')^p.$$

(Note that the coefficients of each monomial in ψ may not be 1)

Kernel trick: we do not need explicit features to calculate inner products.

- Using explicit features: $O(d^p)$
- Using implicit computation: $O(d)$

Kernel Function

The Kernel Function

- **Input space:** \mathcal{X}
- **Feature space:** \mathcal{H} (a Hilbert space, e.g. \mathbb{R}^d)
- **Feature map:** $\psi : \mathcal{X} \rightarrow \mathcal{H}$
- The **kernel function** corresponding to ψ is

$$k(x, x') = \langle \psi(x), \psi(x') \rangle,$$

where $\langle \cdot, \cdot \rangle$ is the inner product associated with \mathcal{H} .

Why introduce this new notation $k(x, x')$?

- We can often evaluate $k(x, x')$ without explicitly computing $\psi(x)$ and $\psi(x')$.

When can we use the kernel trick?

Some Methods Can Be “Kernelized”

Definition

A method is **kernelized** if every feature vector $\psi(x)$ only appears inside an inner product with another feature vector $\psi(x')$. This applies to both the optimization problem and the prediction function.

The SVM Dual is a kernelization of the original SVM formulation.

Optimization:

$$\begin{aligned} \text{maximize} \quad & \sum_{i=1}^n \alpha_i - \frac{1}{2} \sum_{i,j=1}^n \alpha_i \alpha_j y_i y_j \psi(x_j)^T \psi(x_i) \\ \text{s.t.} \quad & \sum_{i=1}^n \alpha_i y_i = 0 \quad \text{and} \quad \alpha_i \in \left[0, \frac{c}{n}\right] \quad \forall i. \end{aligned}$$

Prediction:

$$\hat{f}(x) = \sum_{i=1}^n \alpha_i^* y_i \psi(x_i)^T \psi(x).$$

The Kernel Matrix

Definition

The **kernel matrix** for a kernel k on $x_1, \dots, x_n \in \mathcal{X}$ is

$$K = (k(x_i, x_j))_{i,j} = \begin{matrix} & \langle \phi(x_i), \phi(x_j) \rangle \\ \begin{pmatrix} k(x_1, x_1) & \cdots & k(x_1, x_n) \\ \vdots & \ddots & \cdots \\ k(x_n, x_1) & \cdots & k(x_n, x_n) \end{pmatrix} \end{matrix} \in \mathbb{R}^{n \times n}.$$

- In ML this is also called a **Gram matrix**, but traditionally (in linear algebra), Gram matrices are defined without reference to a kernel or feature map.

$$V_{ij} = \langle v_i, v_j \rangle$$

The Kernel Matrix

- The kernel matrix summarizes all the information we need about the training inputs x_1, \dots, x_n to solve a kernelized optimization problem.
- In the kernelized SVM, we can replace $\psi(x_i)^T \psi(x_j)$ with K_{ij} :

$$\begin{aligned} \text{maximize}_{\alpha} \quad & \sum_{i=1}^n \alpha_i - \frac{1}{2} \sum_{i,j=1}^n \alpha_i \alpha_j y_i y_j K_{ij} \\ \text{s.t.} \quad & \sum_{i=1}^n \alpha_i y_i = 0 \quad \text{and} \quad \alpha_i \in \left[0, \frac{C}{n}\right] \quad i = 1, \dots, n. \end{aligned}$$

Handwritten notes: $K_{n \times n}$ (above the sum), $\langle \psi(x_i), \psi(x_j) \rangle$ (below K_{ij})

Kernel Methods

Given a kernelized ML algorithm (i.e. all $\psi(x)$'s show up as $\langle \psi(x), \psi(x') \rangle$),

- Can swap out the inner product for a new kernel function.
- New kernel may correspond to a **very high-dimensional** feature space.
- Once the kernel matrix is computed, the computational cost **depends on number of data points** n , rather than the dimension of feature space d .
- Useful when $d \gg n$.
- Computing the kernel matrix may still depend on d and the essence of the **trick** is getting around this $O(d)$ dependence.

Example Kernels

Kernels as Similarity Scores

$= \langle \psi(x), \psi(x') \rangle$

$$\cos \theta = \frac{\langle x, x' \rangle}{\|x\| \|x'\|}$$

- Often useful to think of the $k(x, x')$ as a **similarity score** for x and x' .
- We can design similarity functions without thinking about the explicit feature map, e.g. “string kernels”, “graph kernels”.
- How do we know that our kernel functions actually correspond to inner products in some feature space?

How to Get Kernels?

- Explicitly construct $\psi(x) : \mathcal{X} \rightarrow \mathbb{R}^d$ (e.g. monomials) and define $k(x, x') = \psi(x)^T \psi(x')$.
- Directly define the kernel function $k(x, x')$ (“similarity score”), and **verify it corresponds to $\langle \psi(x), \psi(x') \rangle$ for some ψ .**

There are many theorems to help us with the second approach.

Linear Algebra Review: Positive Semidefinite Matrices

Definition

A real, symmetric matrix $M \in \mathbb{R}^{n \times n}$ is **positive semidefinite (psd)** if for any $x \in \mathbb{R}^n$,

$$x^T M x \geq 0.$$

Theorem

The following conditions are each necessary and sufficient for a symmetric matrix M to be positive semidefinite:

- *M can be factorized as $M = R^T R$, for some matrix R .*
- *All eigenvalues of M are greater than or equal to 0.*

Positive Definite Kernel

Definition

A symmetric function $k: \mathcal{X} \times \mathcal{X} \rightarrow \mathbb{R}$ is a **positive definite (pd)** kernel on \mathcal{X} if for any finite set $\{x_1, \dots, x_n\} \in \mathcal{X}$ ($n \in \mathbb{N}$), the kernel matrix on this set

$$K = (k(x_i, x_j))_{i,j} = \begin{pmatrix} k(x_1, x_1) & \cdots & k(x_1, x_n) \\ \vdots & \ddots & \vdots \\ k(x_n, x_1) & \cdots & k(x_n, x_n) \end{pmatrix}$$

is a positive semidefinite matrix.

- Symmetric: $k(x, x') = k(x', x)$
- The kernel matrix needs to be positive semidefinite for **any** finite set of points.
- Equivalent definition: $\sum_{i=1}^n \sum_{j=1}^n \alpha_i \alpha_j k(x_i, x_j) \geq 0$ given $\alpha_i \in \mathbb{R} \forall i$.

Mercer's Theorem

Theorem

A symmetric function $k(x, x')$ can be expressed as an inner product

$$k(x, x') = \langle \psi(x), \psi(x') \rangle$$

for some ψ if and only if $k(x, x')$ is **positive definite**.

- Proving a kernel function is positive definite is typically not easy.
- But we can construct new kernels from valid kernels.

$$\begin{aligned} K &= Q \Lambda Q^T \\ &= (\Lambda^{1/2} Q^T)^T (\Lambda^{1/2} Q^T) \\ \phi(x_i) &= (\Lambda^{1/2} Q^T)[\cdot, i] \end{aligned}$$

Generating New Kernels from Old

- Suppose $k, k_1, k_2 : \mathcal{X} \times \mathcal{X} \rightarrow \mathbb{R}$ are pd kernels. Then so are the following:

$$k_{\text{new}}(x, x') = \alpha k(x, x') \quad \text{for } \alpha \geq 0 \quad (\text{non-negative scaling})$$

$$k_{\text{new}}(x, x') = k_1(x, x') + k_2(x, x') \quad (\text{sum})$$

$$k_{\text{new}}(x, x') = k_1(x, x') k_2(x, x') \quad (\text{product})$$

$$k_{\text{new}}(x, x') = k(\psi(x), \psi(x')) \quad \text{for any function } \psi(\cdot) \quad (\text{recursion})$$

$$k_{\text{new}}(x, x') = f(x)f(x') \quad \text{for any function } f(\cdot) \quad (f \text{ as 1D feature map})$$

- Lots more theorems to help you construct new kernels from old.

- Input space: $\mathcal{X} = \mathbb{R}^d$
- Feature space: $\mathcal{H} = \mathbb{R}^d$, with standard inner product
- Feature map

$$\psi(x) = x$$

- Kernel:

$$k(x, x') = x^T x'$$

Quadratic Kernel in \mathbb{R}^d

- Input space $\mathcal{X} = \mathbb{R}^d$
- Feature space: $\mathcal{H} = \mathbb{R}^D$, where $D = d + \binom{d}{2} \approx d^2/2$.
- Feature map:

$$\psi(x) = (x_1, \dots, x_d, x_1^2, \dots, x_d^2, \sqrt{2}x_1x_2, \dots, \sqrt{2}x_1x_d, \dots, \sqrt{2}x_{d-1}x_d)^T$$

- Then for $\forall x, x' \in \mathbb{R}^d$

$$\begin{aligned}k(x, x') &= \langle \psi(x), \psi(x') \rangle \\ &= \langle x, x' \rangle + \langle x, x' \rangle^2\end{aligned}$$

- Computation for inner product with explicit mapping: $O(d^2)$
- Computation for implicit kernel calculation: $O(d)$.

Polynomial Kernel in \mathbb{R}^d

- Input space $\mathcal{X} = \mathbb{R}^d$

- Kernel function:

$$k(x, x') = (1 + \langle x, x' \rangle)^M$$

- Corresponds to a feature map with all monomials up to degree M .
- For any M , computing the kernel has same computational cost
- Cost of explicit inner product computation grows rapidly in M .

Radial Basis Function (RBF) / Gaussian Kernel

Input space $\mathcal{X} = \mathbb{R}^d$

$$k(x, x') = \exp\left(-\frac{\|x - x'\|^2}{2\sigma^2}\right),$$

where σ^2 is known as the bandwidth parameter.

- Probably the most common nonlinear kernel.
- Does it act like a similarity score?
- Why “radial”?
- Have we departed from our “inner product of feature vector” recipe?
 - Yes and no: corresponds to an infinite dimensional feature vector

Remaining Questions

Our current recipe:

- Recognize kernelized problem: $\psi(x)$ only occur in inner products $\psi(x)^T \psi(x')$
- Pick a kernel function (“similarity score”)
- Compute the kernel matrix (n by n where n is the dataset size)
- Optimize the model and make predictions by accessing the kernel matrix

Next: When can we apply kernelization?
