Intro Question

Question

We are given the data set $(x_1, y_1), \ldots, (x_n, y_n)$ where $x_i \in \mathbb{R}^d$ and $y_i \in \mathbb{R}$. We want to fit a **linear function** to this data by performing **empirical risk minimization**. More precisely, we are using the hypothesis space $\mathcal{F} = \{h_{\theta}(x) = \theta^T x \mid \theta \in \mathbb{R}^d\}$ and the loss function $\ell(a, y) = (a - y)^2$. Given an initial guess $\tilde{\theta}$ for the empirical risk minimizing parameter vector, how could we improve our guess?

Intro Solution

Solution

• The empirical risk is given by

$$J(\theta) := \hat{R}_n(h_{\theta}) = \frac{1}{n} \sum_{i=1}^n \ell(h_{\theta}(x_i), y_i) = \frac{1}{n} \sum_{i=1}^n (\theta^T x_i - y_i)^2 = \frac{1}{n} ||X\theta - y||_2^2,$$

where $X \in \mathbb{R}^{n \times d}$ is the matrix whose *i*th row is given by x_i^T .

• Can improve a non-optimal guess $\tilde{\theta}$ by taking a small step in the direction of the negative gradient $-\nabla J(\theta)$.

Intuition

- Why don't we directly compute the derivative $\frac{\partial}{\partial \theta} J(\theta, y)$ and solve for θ^* that makes $\frac{\partial}{\partial \theta} J(\theta^*, y) = 0$.
 - But what if the analytical solution for $\frac{\partial}{\partial \theta} J(\theta^*, y) = 0$ is computationally intractable?
- We can improve the an initial guess θ_0 by iteratively "updating" it using the gradient of the loss $\nabla J(\theta)$.
- This process will give us a "good enough" approximation for θ^* .
- To do so, we need to know how to calculate the gradient $J(\theta^*, y)$.

Directional Derivative

Definition

Let $f: \mathbb{R}^n \to \mathbb{R}$. The directional derivative f'(x; u) of f at $x \in \mathbb{R}^n$ in the direction $u \in \mathbb{R}^n$ is given by

$$f'(x; u) = \lim_{h \to 0} \frac{f(x + hu) - f(x)}{h}.$$

- We say that u is a descent direction of f at x if f'(x; u) < 0.
- Taking a small enough step in a descent direction causes the function value to decrease.

Partial Derivative

- Let $e_i = (0, 0, \dots, 0, 1, 0, \dots, 0)$ denote the *i*th standard basis vector.
- The *i*th *partial derivative* is defined to be the directional derivative along e_i .
- It can be written many ways:

$$f'(x; e_i) = \frac{\partial}{\partial x_i} f(x) = \partial_{x_i} f(x) = \partial_i f(x).$$

• What is the intuitive meaning of $\partial_{x_i} f(x)$? For example, what does a large value of $\partial_{x_3} f(x)$ imply?

Differentiability and Gradients

• We say a function $f: \mathbb{R}^n \to \mathbb{R}$ is differentiable at $x \in \mathbb{R}^n$ if

$$\lim_{v \to 0} \frac{f(x+v) - f(x) - g^{T}v}{\|v\|_{2}} = 0,$$

for some $g \in \mathbb{R}^n$. (Proof: page 8 of **19ML notes**)

 If it exists, this g is unique and is called the gradient of f at x with notation

$$g = \nabla f(x)$$
.

It can be shown that

$$\nabla f(x) = \begin{pmatrix} \partial_{x_1} f(x) \\ \vdots \\ \partial_{x_n} f(x) \end{pmatrix}.$$

Computing Gradients

Question

Compute the gradient $\nabla f(\theta) \in \mathbb{R}^2$ for the following function:

$$f(\theta) = \theta_0^2 + 2\theta_0\theta_1^3$$

The gradient of this function can be computed as following:

$$\frac{\partial}{\partial \theta_0} = 2\theta_0 + 2\theta_1^3$$

$$\frac{\partial}{\partial \theta_1} = 6\theta_0 \theta_1^2$$

$$\nabla f(\theta) = \begin{bmatrix} 2\theta_0 + 2\theta_1^3 \\ 6\theta_0\theta_1^2 \end{bmatrix}$$

Computing Gradients

Question

Compute the gradient $\nabla J(\theta) \in \mathbb{R}^d$ for

$$J(\theta) = \|X\theta - y\|_2^2$$

where $X \in \mathbb{R}^{n \times d}$, $y \in \mathbb{R}^n$, $\theta \in \mathbb{R}^d$.

In homework2, we will show that

$$\nabla J(\theta) = 2(X^T X \theta - X^T y) = 2X^T (X \theta - y)$$

Gradient Checker

- So far we have worked with relatively simple functions where it is straight-forward to compute the gradient.
- For more complex functions, the gradient computation can be notoriously difficult to debug and get right. Example from www. quora.com/What-is-the-most-complex-equation-in-the-world.
- How can we test if our gradient computation is correct?

```

Gradient Checker

• Recall the mathematical definition of the derivative as:

$$\frac{\partial}{\partial \theta} f(\theta) = \lim_{\epsilon \to 0} \frac{f(\theta + \epsilon) - f(\theta - \epsilon)}{2\epsilon}$$

- We can approximate the gradient (left hand side) using the equation on the right hand side by setting ϵ to a small constant, say $\epsilon = 10^{-4}$.
- Now let's expand this method to deal with vector input $\theta \in \mathbb{R}^d$. Let's say we want to verify out gradient at dimension i $(\nabla f(\theta))_i$. We can make use of one-hot vector e_i in which all dimension except the ith are 0 and the ith dimension has a value of 1: $e_i = [0, 0, ..., 1, ..., 0]^T$
- The gradient at ith dimension can be then approximated as

$$[\nabla f(\theta)]^{(i)} \approx \frac{f(\theta + \epsilon e_i) - f(\theta - \epsilon e_i)}{2\epsilon}$$

Recap

- To find a good decision function we will minimize the empirical loss on the training data.
- Having fixed a hypothesis space parameterized by θ , finding a good decision function means finding a good θ .
- Given a current guess for θ , we will use the gradient of the empirical loss (w.r.t. θ) to get a local linear approximation.
- If the gradient is non-zero, taking a small step in the direction of the negative gradient is guaranteed to decrease the empirical loss.
- This motivates the minimization algorithm called gradient descent.

Coding Exercise

In the provided notebook, we will use Python to:

- calculate the gradient for two example functions
- implement the gradient checker
